Abstract

Results are presented for Round 44 of the International Association of Geoanalysts' Proficiency Testing programme for analytical geochemistry laboratories. The test material distributed in this round of GeoPT was the Calcareous shale, ShCX-1, supplied by Dr Stephen Wilson of the U.S. Geological Survey. In this report, the data contributed by 94 laboratories are listed, together with an assessment of consensus values, consequent z-scores and charts to show the distribution of contributed results and the overall performance of participating laboratories.

Introduction

This forty-fourth round of the international proficiency testing programme, GeoPT, was conducted in a similar manner to earlier rounds. The programme is designed to be part of the routine quality assurance procedures employed by analytical geochemistry laboratories. The programme is organised by the International Association of Geoanalysts and is conducted in accordance with a published protocol, recently revised (IAG, 2018). The overall aim of the programme is to provide participating laboratories with z-score information for their reported measurement results so that each laboratory can decide whether the quality of their data is satisfactory in relation both to their chosen fitness-for-purpose criteria

and to the results submitted by other laboratories contributing to the round. In circumstances where z-scores are unsatisfactory, a participating laboratory is encouraged to investigate for unsuspected analytical bias and to take corrective action if this appears justified.

Steering Committee for Round 44: P.C. Webb (results coordinator), M. Thompson (statistical advisor), P.J. Potts, C.J.B. Gowing (analytical advisors) and S.A. Wilson (provision of ShCX-1).

Timetable for Round 44:

Distribution of sample: September 2018

Results submission deadline: 13th December 2018

Release of report: January 2019

Test Material details

GeoPT44: The Calcareous shale test material, ShCX-1, was prepared at the U.S. Geological Survey under the direction of Dr Stephen Wilson. The test material was evaluated for homogeneity by the originator, and as a result, the sample was considered suitable for use in this proficiency test.

Submission of results

A total of 3184 results (excluding zeros) were submitted for GeoPT44 (ShCX-1) by 94 laboratories as listed in

Table 1. Measurement results that were designated by the participating laboratory as data quality 1 (see **Z-score analysis section** below for explanation) are shown in bold and results of data quality 2 are shown underlined. Results from all laboratories submitting data were used to assess respective consensus values. Four laboratories reported values of '0' (i.e. zero) for this round contrary to our ongoing instructions. These values are excluded from consideration in the data assessment process. It is suspected that two laboratories reported both C(org) and C(tot) in g/100g instead of mg/kg and three laboratories made the same form of error in submitting S data. We must remind analysts reporting results that these measurements and those of all trace constituents should be reported in mg/kg. Suspected invalid results cannot be altered or removed once they have been submitted and corresponding z-scores will be adversely affected.

Assigned values and results summary

Following procedures described in earlier rounds, and detailed fully in the GeoPT protocol (2018), robust statistical procedures were used to derive consensus values for measurands in this test material: these consensus values being judged to be the best available estimates of the true composition. Values were assigned on the basis that: i) sufficient laboratories had contributed data for estimating a measurand, ii) visual assessment gave confidence that a substantial proportion of the results distribution was symmetrically disposed about the consensus, iii) the ratio of the uncertainty in the location estimate to the target precision is an acceptably small value, and iv) an evaluation of measurement results by procedure – including both methods of analysis and sample preparation – indicated no detectable procedural bias among measurement results from which the consensus was derived. Where these criteria are not fully met, values may be credited with 'provisional' rather than 'assigned' status.

These assessments also involve examining the distribution of results from barcharts of data contributed for each measurand (as presented in Figures 1 and 2), and a variety of plots – permitting discrimination of data by procedure of analysis and sample preparation – as

developed by Thomas Meisel using the Shiny App (<https://www.shinyapps.io>) linked to the statistical package 'R'. This enables us, when necessary, to refine the selection of consensus values by taking account of data distributions according to analytical procedure.

Some datasets were normally distributed, showing remarkable symmetry with relatively little dispersion of data, and consequently, in 6 cases, the robust mean was used to define an appropriate consensus value. However, for 38 datasets that were very slightly skewed, medians provided a more satisfactory estimator of consensus values. For 14 datasets that were more severely skewed, where the median did not provide a sufficiently symmetrical distribution of data about the consensus, a mode was preferred to estimate the location of the consensus.

Use of modes as location estimators helped to avoid bias due to asymmetric tailing in several datasets. In nine cases, modes were sufficiently well defined by a consensus of results acquired by appropriate techniques to justify their designation as assigned values.

Procedures used to determine modes included the estimation of the mass fraction corresponding to the maximum value of the kernel density distribution for the dataset as described by Thompson (2017) and some using the Lientz mode (Lientz, 1969) as provided by the "modeest" package which runs in 'R' (<https://cran.r-project.org/web/packages/modeest/modeest.pdf>). Modes are suitably robust location estimators that can provide consensus values representing the most coherent part of a data distribution where data are symmetrically disposed, although the dataset as a whole may be asymmetric.

In those cases where a mode was considered to be the most appropriate location estimator, it was as a consequence of an overall asymmetric distribution of results involving tails of somewhat variable data. Experience has shown that the reason for a high tail is frequently because measurement results have been reported for mass fractions (e.g. for Co, Cr, Pb, Sc, Sn and W in ShCX-1) close to the detection limit for the technique (e.g. for XRF) with the consequence that those data have poor precision and accuracy. Mode evaluation

can successfully de-emphasise such results when estimating a consensus, but in many of these cases only provisional status could be credited.

For Na₂O the low mass fraction was almost certainly the reason for a high dispersion of data which extended well beyond our fitness-for-purpose targets and therefore no value could be derived for the purpose of calculating z-scores.

An unusually low tail was observed for the K₂O dataset, similar to that observed in results contributed for ShTX-1, the calcareous organic-rich shale, which was the subject of GeoPT40A. In both cases, the test materials contained relatively low mass fractions of K₂O but high CaO and carbonate components. Following a personal communication from Marcus Burnham (Ontario Geological Survey) with details of an earlier investigation, it is considered possible that volatilisation of potassium may occur when a test sample of this type is calcined at more than 925°C. This may then affect K₂O measurements when elemental analysis is carried out on the test portion already used for loss on ignition determination. Unfortunately, the information about procedures as supplied by most participants is not sufficiently detailed to be able to confirm our understanding of the cause of this effect. We therefore recommend that analysts respond to our plea in the Addendum of this report to update their procedural information so that we have a more complete understanding of the influence of methods on variations in contributed datasets in the future.

Table 2 lists assigned and provisional values for 11 major components and 47 trace elements in GeoPT44 (ShCX-1). Barcharts for the 58 measurands of GeoPT44 that were judged to have satisfactory distributions for consensus values to be designated as assigned or provisional values are shown in Figure 1. These are: SiO₂, TiO₂, Al₂O₃, Fe₂O₃T, MnO, MgO*, CaO, K₂O*, P₂O₅, CO₂*, LOI, Ag, As, Ba, Be, Bi*, C(tot), Cd, Ce, Co*, Cr, Cs, Cu, Dy, Er, Eu, Ga, Gd, Hf, Ho, La, Li, Lu, Mo, Nb, Nd, Ni, Pb*, Pr, Rb, Sb, Sc, Se*, Sm, Sn*, Sr, Ta, Tb, Th, Tl, Tm, U, V, W*, Y, Yb, Zn and Zr. Of these, provisional values were given to the 9 analytes marked '*'. Instances of provisional status were

recorded because either: i) a relatively small number of results (<15) contributed to the consensus, or ii) the results were unduly dispersed in relation to the target value, or iii) the distribution of results was significantly skewed.

Bar charts for the 11 analytes: Fe(II)O, Na₂O, H₂O⁺, Br, C(org), Cl, F, Ge, Hg, In and S are plotted in Figure 2 for information only, as the data were either insufficient in number, or the distribution was too highly skewed or too variable for the reliable determination of a consensus for the estimation of z-scores.

Z-score analysis

As in previous rounds, laboratories were invited to choose one of two performance standards against which their analytical results would be judged:

Data quality 1 for laboratories working to a 'pure geochemistry' standard of performance, where analytical results are designed for geochemical research and where care is taken to provide data of high precision and accuracy, sometimes at the expense of a reduced sample throughput rate. For GeoPT44, 1418 results of data quality 1 were submitted.

Data quality 2 for laboratories working to an 'applied geochemistry' standard of performance, where, although precision and accuracy are still important, the main objective is to provide results on large numbers of samples collected, for example, as part of geochemical mapping projects or geochemical exploration programmes. For GeoPT44, 1766 results of data quality 2 were submitted.

The target standard deviation (H_a) for each measurand assessed was calculated from a modified form of the Horwitz function as follows:

$$H_a = k \cdot X_a^{0.8495}$$

Where X_a is the mass fraction of the element; the factor $k = 0.01$ for pure geochemistry laboratories and $k = 0.02$ for applied geochemistry laboratories.

Z-scores were calculated for each elemental measurement submitted by each laboratory from:

$$z = [X - X_a] / H_a$$

Where X is the contributed measurement result, X_a is the assigned value and H_a is the target standard deviation (all as mass fractions). Z-score values for results contributed to GeoPT44 are listed in Table 3. Results designated as data quality 1 are shown in bold: results of data quality 2 are shown underlined. Z-scores derived from provisional values of measurands are shown in italics.

Participating laboratories are invited to assess their performance using the following criteria:–

Z-score results in the range $-2 < z < 2$ are considered to be 'satisfactory' (in the sense that no action is called for by the participant). If the z-score for any element falls outside this range, especially if it is outside the range $-3 < z < 3$, laboratories are advised to examine their procedures, and if necessary, take action to ensure that determinations are not subject to unsuspected analytical bias.

Overall performance

A summary of the overall performance of individual laboratories for this round is plotted in multiple z-score charts in Figure 3. In these charts, the z-score performance for each element is distinguished by symbols that make it easy to identify whether the results were satisfactory or gave z-scores that exceeded the action limits. This chart is designed to help individual laboratories judge their overall performance in this proficiency testing round. Participants should always review their z-scores in accordance with their own fitness-for-purpose criteria.

Participation in future rounds

The benefit from proficiency testing arises from regular participation and laboratories are invited to contribute to Round 45, the test sample for which will be distributed during March 2019.

Acknowledgements

The authors thank Cynthia Turner and Andrea Mills (BGS) for much-valued assistance in distributing this sample and Thomas Meisel for development of software which has greatly assisted the investigation of data according to analytical procedure and facilitated analysis

of datasets involving modes derived according to Thompson (2017) and as provided in the package “modeest”, which is available as an “R” package (<https://cran.r-project.org/web/packages/modeest/modeest.pdf>).

ADDENDUM

— AN IMPORTANT NOTICE TO ANALYSTS

Explicit advice to analysts regarding reporting of procedures involving ignition and fusion:

For some time we have requested that analysts reporting measurement results for procedures involving fusion, sintering or ignition, particularly LOI determinations, specify the temperature used and where appropriate, the end-point criterion, e.g. the duration of ignition. This information should be supplied, in descriptions of your relevant **Procedures**, as **Additional Details**.

In this round we have seen the possibility that many underestimated K_2O values were the result of volatilisation of potassium, possibly when ignition is undertaken on the test material prior to fusion. Unfortunately it has not been possible to investigate this further, because the relevant details were not included in the procedural details provided by many participating laboratories. We urge analysts to make efforts to provide these details for future rounds, as it will assist in assessing data variations.

Note also, that a large number of laboratories are listing

their procedure for determining LOI as the same as that employed for major elements, rather than providing separate, specific details. It is important to provide information that is appropriate for every analyte.

In addition it would help if details of gravimetric

procedures were included under **Analytical Technique details** rather than under **Sample Preparation details**.

For gravimetric analysis, other than drying, which should in any case be carried out according to our instructions, there is no other sample preparation involved.

Bold entries are Data Quality 1 - Underlined entries are Data Quality 2 - *Entries in italics* are derived from Provisional Values.

GeoPT44 - Barchart for Er

GeoPT44 - Barchart for Eu

GeoPT44 - Barchart for Ga

GeoPT44 - Barchart for Gd

GeoPT44 - Barchart for Hf

GeoPT44 - Barchart for Ho

Figure 1: GeoPT44 - Calcareous shale, ShCX-1. Data distribution charts for elements for which values were assigned or provisional values given for guidance. Horizontal lines show the limits for $-2 < z < 2$ for pure geochemistry labs (solid lines) and $-2 < z < 2$ for applied geochemistry labs (pecked lines).

Figure 2: GeoPT44 - Calcareous shale, ShCX-1. Data distribution charts provided for information only for elements for which values could not be assigned.

Multiple Z-Score Chart for GeoPT44

Figure 3: GeoPT44 - Calcareous shale, ShCX-1. Multiple z-score charts for laboratories participating in the GeoPT44 round. Symbols indicate whether or not an elemental result complies with the $-2 < z < +2$ criteria (see key).

Multiple Z-Score Chart for GeoPT44

Figure 3: GeoPT44 - Calcareous shale, ShCX-1. Multiple z-score charts for laboratories participating in the GeoPT44 round. Symbols indicate whether or not an elemental result complies with the $-2 < z < +2$ criteria (see key).
