Abstract

Results are presented for Round 44A of the International Association of Geoanalysts' Proficiency Testing programme for analytical geochemistry laboratories. The test material distributed in this round of GeoPT was the Carbonate mudrock, CM-1, supplied by the Central Geological Laboratory, Mongolia. In fact, this test material is a certified reference material, the limestone ML-3 (code IAG/CGL 020), renamed to ensure complete anonymity. In this report, the data contributed by 91 laboratories are listed, together with an assessment of consensus values, consequent *z*-scores and charts to show the distribution of contributed results and the overall performance of participating laboratories.

Introduction

This forty-fourth round of the international proficiency testing programme, GeoPT, was conducted in a similar manner to earlier rounds. The programme is designed to be part of the routine quality assurance procedures employed by analytical geochemistry laboratories. The programme is organised by the International Association of Geoanalysts and is conducted in accordance with a published protocol, recently revised (IAG, 2018). The overall aim of the programme is to provide participating laboratories with *z*-score information for their reported measurement results from which each can decide whether the quality of their data is satisfactory in relation both to their chosen fitness-for-purpose criteria and to the results submitted by other laboratories

contributing to the round. In circumstances where *z*-scores are unsatisfactory, a participating laboratory is encouraged to investigate for unsuspected analytical bias and to take corrective action if this appears justified.

Steering Committee for Round 44A: P.C. Webb (results coordinator), M. Thompson (statistical advisor), P.J. Potts and C.J.B. Gowing (analytical advisors).

Timetable for Round 44A:

Distribution of sample: September 2018

Results submission deadline: 13th December 2018

Release of report: January 2019

Test Material details

GeoPT44A: The Carbonate mudrock test material, CM-1, is in fact, the certified reference material (CRM) known as Limestone ML-3 (coded IAG/CGL 020), obtained from the Central Geological Laboratory, Mongolia. Supplied in 100g portions, it was repackaged at BGS Keyworth, whereby portions were combined in pairs and divided 8 ways to provide 140 packets of test material. The test material had been evaluated for homogeneity as part of the IAG/CGL certification process, detailed on the Certificate of Analysis for IAG/CGL 020, ML-3 (Limestone). As a result, the sample was considered suitable for use in this proficiency test.

Submission of results

A total of 2922 results were submitted for GeoPT44A (CM-1) by 91 laboratories as listed in Table 1. Results from all laboratories submitting data were used to assess respective assigned values. Four laboratories reported values of '0' (i.e. zero) for this round contrary to our ongoing instructions. These values are excluded from consideration in the data assessment process. It is suspected that one laboratory reported C(org) in g/100g instead of mg/kg and two laboratories made the same form of error in submitting S data. We must remind analysts reporting results that measurements for these analytes and those of all trace constituents should be reported in mg/kg. Suspected invalid results cannot be altered or removed once they have been submitted and corresponding z-scores will be adversely affected.

Assigned values and results summary

Following procedures described in earlier rounds, and detailed fully in the GeoPT protocol (2018), robust statistical procedures were used to derive consensus values for measurands in this test sample: these consensus values being judged to be the best available estimates of the true composition. Values were assigned on the basis that: i) sufficient laboratories had contributed data for estimating a measurand, ii) visual assessment gave confidence that a substantial proportion of the results distribution was symmetrically disposed about the consensus, iii) the ratio of the uncertainty in the location estimate to the target precision is an acceptably small value, and iv) an evaluation of measurement results by procedure – including both methods of analysis and sample preparation – indicated no detectable procedural bias among measurement results from which the consensus was derived. Where these criteria are not fully met, values may be credited with 'provisional' rather than 'assigned' status.

These assessments also involve examining the distribution of results from barcharts of data contributed for each measurand (as presented in Figures 1 and 2), and from a variety of plots – permitting discrimination of data by procedure of analysis and sample preparation – as developed by Thomas Meisel using the Shiny App (<https://www.shinyapps.io>) linked to the statistical

package 'R'. This enables us, when necessary, to refine the selection of consensus values by taking account of data distributions according to analytical procedure.

Many datasets were normally distributed, showing remarkable symmetry with relatively little dispersion of data, and consequently, in 13 cases, the robust mean was used to define an appropriate consensus value. However, for 25 datasets that were very slightly skewed, medians provided a more satisfactory estimator of consensus values. For 12 datasets that were more severely skewed, where the median did not provide a sufficiently symmetrical distribution of data about the consensus, a mode was preferred to estimate the location of the consensus.

Use of modes as location estimators helped to avoid bias due to asymmetric tailing in several datasets. In six cases, modes were sufficiently well defined by a consensus of results acquired by appropriate techniques to justify their designation as assigned values.

Procedures used to determine modes mostly involved the estimation of the mass fraction corresponding to the maximum value of the kernel density distribution for the dataset as described by Thompson (2017) and a few using the Lientz mode (Lientz, 1969) as provided by the "modeest" package which runs in 'R' (<https://cran.r-project.org/web/packages/modeest/modeest.pdf>). Modes are suitably robust location estimators that can provide consensus values representing the most coherent part of a data distribution where data are symmetrically disposed, although the dataset as a whole may be asymmetric.

Analysis of data distributions took into account that the test material, being an impure limestone, contains very low mass fractions of many analytes, which has a number of consequences. In particular, measurement results for 'major' elements at low mass fractions are frequently reported with insufficient decimal places, creating a stepped or pixellated effect in barcharts and an artificial impression that results distributions could be multimodal. This effect has been illustrated previously in Thompson et al. (2015). In CM-1, for example, the TiO₂ data distribution has major steps at 0.04 and 0.05 g/100g (see Figure 1, p. 16) because many laboratories

reported TiO₂ to only two decimal places. There are also smaller steps at increments of 0.001 g/100g, suggesting that provision of even more decimal places would be beneficial in programmes, such as proficiency tests, where evaluations of test material composition are undertaken. For TiO₂, this situation was to a large extent responsible for awarding a provisional rather than assigned status to the consensus value. Similar, but slightly less striking stepped effects are observed for MnO and K₂O data distributions. On account of very low mass fractions involved, similar effects are also apparent for some trace elements. For example, Tm was reported to only two decimal places by many laboratories, and hence there is an artificial impression of multiple modality in the results distribution, because of the numbers of results quoted as 0.04 and 0.05 mg/kg. We strongly recommend that results are presented to a minimum of three significant figures.

It is also necessary to take into account the consequences of inappropriate methods of analysis, which can bias the uncritical derivation of a consensus if unsophisticated statistical methods are employed. In *GeoPT* we aim to derive optimal consensus values using robust methods and expert judgement, as detailed in our operating protocol (IAG, 2018). Thus distributions of results involving variable but high values where the true value is close to the detection limit of the method are commonly observed, and due regard must be taken to minimise their effect when establishing a consensus. Sometimes, but not always, the reason for a high tail is because XRF data had been reported for mass fractions close to the detection limit for the technique. Some datasets feature low tails due to inadequate dissolution of refractory minerals by some acid digestion procedures, as is often the case for Hf and Zr, which was reported in Potts et al. (2015). These various considerations are particularly relevant for Ba, Ce, Cr, La, Pb, Sb, Sc, Sn, Ta, Th, W, Zn and Zr in CM-1, where an appropriate consensus judged to be optimal could be derived only through estimation of the mode. In many of these cases, only provisional status could be credited. For As, Cd, Co, Cu, Mo and Ni, an insufficient proportion of measurements contributed to the

consensus and it was considered unsafe to recognise even a provisional value.

Table 2 lists assigned and provisional values for 11 major/minor components and 39 trace elements in *GeoPT44A* (CM-1). Barcharts for the 50 analytes of *GeoPT44A* that were judged to have satisfactory distributions for consensus values to be designated as assigned or provisional values are shown in Figure 1. These are: SiO₂, TiO₂*, Al₂O₃, Fe₂O₃T, MnO, MgO, CaO, K₂O, P₂O₅, CO₂*, LOI, Ba, Be, Bi*, C(tot), Ce, Cr*, Cs, Dy, Er, Eu, Ga, Gd, Hf*, Ho, La, Li, Lu, Nb, Nd, Pb, Pr, Rb, Sb, Sc*, Sm, Sn*, Sr, Ta, Tb, Th, Tl, Tm, U, V, W, Y, Yb, Zn* and Zr*. Of these, provisional values were given to the 9 analytes marked '*'.

Instances of provisional status were recorded because either: i) a relatively small number of results (<15) contributed to the consensus, or ii) the results were unduly dispersed in relation to the target value, or iii) the distribution of results was significantly skewed.

Bar charts for the 15 analytes: Fe(II)O, Na₂O, H₂O⁺, Ag, As, C(org), Cd, Cl, Co, Cu, F, Ge, Mo, Ni and S are plotted in Figure 2 for information only, as the data were either insufficient in number, or the distribution was too highly skewed or too variable for reliable determination of a consensus for the estimation of z-scores.

Z-score analysis

As in previous rounds, laboratories were invited to choose one of two performance standards against which their analytical results would be judged:

Data quality 1 for laboratories working to a 'pure geochemistry' standard of performance, where analytical results are designed for geochemical research and where care is taken to provide data of high precision and accuracy, sometimes at the expense of a reduced sample throughput rate. For *GeoPT44A*, 1374 results of data quality 1 were submitted.

Data quality 2 for laboratories working to an 'applied geochemistry' standard of performance, where, although precision and accuracy are still important, the main objective is to provide results on large numbers of samples collected, for example, as part of geochemical mapping projects or geochemical exploration

programmes. For GeoPT44A, 1548 results of data quality 2 were submitted.

The target standard deviation (H_a) for each measurand assessed was calculated from a modified form of the Horwitz function as follows:

$$H_a = k \cdot X_a^{0.8495}$$

Where X_a is the mass fraction of the element; the factor $k = 0.01$ for pure geochemistry laboratories and $k = 0.02$ for applied geochemistry laboratories.

Z-scores were calculated for each elemental measurement submitted by each laboratory from:

$$z = [X - X_a] / H_a$$

Where X is the contributed measurement result, X_a is the assigned value and H_a is the target standard deviation (all as mass fractions). Z-score values for results contributed to GeoPT44A are listed in Table 3. Results designated as data quality 1 are shown in bold: results of data quality 2 are shown underlined. Z-scores derived from provisional values are shown in italics.

Participating laboratories are invited to assess their performance using the following criteria:–

Z-score results in the range $-2 < z < 2$ are considered to be 'satisfactory' (in the sense that no action is called for by the participant). If the z-score for any element falls outside this range, especially if it is outside the range $-3 < z < 3$, laboratories are advised to examine their procedures, and if necessary, take action to ensure that determinations are not subject to unsuspected analytical bias.

Overall performance

A summary of the overall performance of individual laboratories for this round is plotted in multiple z-score charts in Figure 3. In these charts, the z-score performance for each element is distinguished by symbols that make it easy to identify whether the results were satisfactory or gave z-scores that exceeded the action limits. This chart is designed to help individual laboratories judge their overall performance in this proficiency testing round. Participants should always review their z-scores in accordance with their own fitness-for-purpose criteria.

Participation in future rounds

The benefit from proficiency testing arises from regular participation and laboratories are invited to contribute to Round 45, the test sample for which will be distributed during March 2019.

Acknowledgements

The authors thank Cynthia Turner and Andrea Mills (BGS) for much-valued assistance in distributing this sample and Thomas Meisel for development of software which has greatly assisted the investigation of data according to analytical procedure and facilitated analysis of datasets involving modes derived according to Thompson (2017) and as provided in the package “modeest”, which is available as an “R” package (<https://cran.r-project.org/web/packages/modeest/modeest.pdf>).

ADDENDUM

— AN IMPORTANT NOTICE TO ANALYSTS

Repeat warning to analysts regarding reporting of procedures involving ignition and fusion:

It is necessary to reiterate that in the *Instructions for Analysts* accompanying your samples, there were specific requests to provide **additional details** for procedures involving **fusion, sintering or ignition**, particularly LOI determinations. Specification of temperature is required for all forms of fusion and the end-point criterion for LOI determinations.

Our thanks to those who have already complied with this request, but it appears that in many cases it has been ignored. We would appreciate your cooperation in

providing these details for future rounds, as it will assist in assessing data variations.

Note also, that a large number of laboratories are listing their procedure for determining LOI as the same as that employed for major elements, rather than providing separate, specific details. It is important to provide analytical procedural information that is appropriate for every analyte.

In addition it would help if details of gravimetric procedures were included under Analytical Technique details rather than under Sample Preparation details. For gravimetric analysis, other than drying, which should in any case be carried out according to our instructions, there is no other sample preparation involved.

GeoPT41

Webb, P.C., Thompson, M., Potts, P.J, Gowing, C.J.B. and Wilson, S.A. (2017)
GeoPT41 - an international proficiency test for analytical geochemistry laboratories - report on round 41 (Andesite, ORA-1) / July 2017.
International Association of Geoanalysts: Unpublished report.

GeoPT41A

Webb, P.C., Thompson, M., Potts, P.J, Gowing, C.J.B. and Wilson, S.A. (2017)
GeoPT41A - an international proficiency test for analytical geochemistry laboratories - report on round 41A (Mineralized stream sediment, SSCO-1) / July 2017. International Association of Geoanalysts: Unpublished report.

GeoPT42

Webb, P.C., Thompson, M., Potts, P.J., Gowing, C.J.B. and Burnham, M. (2018)
GeoPT42 – an international proficiency test for analytical geochemistry laboratories – report on round 42 (Queenston shale, QS-1) / January 2018. International Association of Geoanalysts: Unpublished report.

GeoPT43

Webb, P.C., Potts, P.J., Thompson, M. and Gowing, C.J.B. (2018)
GeoPT43 – an international proficiency test for analytical geochemistry laboratories – report on round 43 (Dolerite, ADS-1) / July 2018. International Association of Geoanalysts: Unpublished report.

Bold entries are Data Quality 1 - Underlined entries are Data Quality 2 - Entries in italics are derived from Provisional Values.

Figure 1: GeoPT44A - Carbonate mudrock, CM-1. Data distribution charts for elements for which values were assigned or provisional values given for guidance. Horizontal lines show the limits for $-2 < z < 2$ for pure geochemistry labs (solid lines) and $-2 < z' < 2$ for applied geochemistry labs (pecked lines).

Figure 2: GeoPT44A - Carbonate mudrock, CM-1. Data distribution charts provided for information only for elements for which values could not be assigned.

Multiple Z-Score Chart for GeoPT44A

Figure 3: GeoPT44A - Carbonate mudrock, CM-1. Multiple z-score charts for laboratories participating in the GeoPT44 A round. Symbols indicate whether or not an elemental result complies with the $-2 < z < +2$ criteria (see key).

Multiple Z-Score Chart for GeoPT44A

Figure 3: GeoPT44A - Carbonate mudrock, CM-1. Multiple z-score charts for laboratories participating in the GeoPT44 A round. Symbols indicate whether or not an elemental result complies with the -2<z<+2 criteria (see key).
