

G-probe 9 Summary Report
May 2013
Stephen Wilson

A total of ten labs submitted final results during this stage of the G-probe 9 study. Technique breakdown was seven labs used LA-ICP-MS, and two used SEM and one EPMA. At the time of data analysis two labs had yet to submit their final results. When results from these labs are provided their Z-scores will be calculated but the summary results will not be modified. The material used in this study was the glass version of USGS reference material AGV-2. Conversion of AGV-2 to a glass (AGV-2G) was unexpected due to the high SiO₂ content of this material. Previous melting experiments had indicated that an SiO₂ content of 55% was the limit of USGS capabilities due to the high viscosity of the molten material. A viscous melt is problematic due to difficulties encountered in mixing during the melting stage and transferring the contents from the reaction vessel to the cooling container. It is believed that the moderate levels of alkali elements in AGV-2 helped lower the viscosity of the melted material.

Results from chromium analysis in this sample are worthy of comment. In the case of Cr there was a large variation in the dataset due to the contributions from a single laboratory. This results in a study mean concentration of 232 ppm +/- 508 ppm. This results in the standard deviation range extending into negative concentrations. Eliminating results from the single lab resulted in a mean concentration of 20 ppm +/- 10.1 ppm and a more normal distribution of chromium results. If you have any questions or comments about this study please forward them to me at your earliest convenience.

Below you will find summary results for each element studied in this test. In the element diagrams you will find information for each technique providing a value. Also included is the target value (◆) and calculated precision ($X \pm Ha$) (◊) based on the Horowitz equation. A figure is also presented representing the data compilation for the entire study when more than one technique reported values. The study average is represented by ■, the standard deviation of the average by ■ and the maximum and minimum values by □. This study average is calculated primarily for the analysis of the major elements where multiple techniques provided data. For each technique an average value is presented (ex LA-ICP-MS, ▲) as well as ± one standard deviation (ex LA-ICP-MS, ▲), and the maximum and minimum values reported (ex LA-ICP-MS, ▲). For one element (Cr) the diagram extends into a negative value along the X axis.

Table 1. Symbols used on figures 1 through 52

<u>Symbol type</u>		<u>Represents</u>
Large solid symbol,	●	Study or method average
Small solid symbol,	●	Study or method one standard deviation
Large open symbol,	○	Study or method Maximum or Minimum

Table 2. Summary results for GP-9, AGV-2G

Oxide	Xa % m/m	Ha % m/m	s.d.m. % m/m	GP-9 AVG. % m/m	Max % m/m	Min % m/m
SiO2	59.3	1.28	4.043	58.92	63.2	48.56

Xa = Target value - USGS certificate value for AGV-2, confirmed by bulk analysis of glass

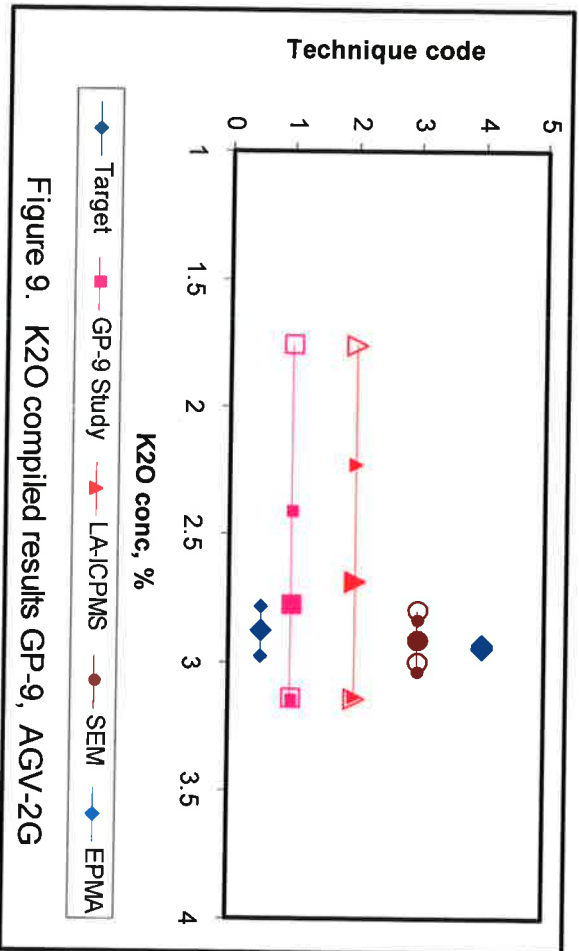

Ha = Target precision calculated using modified version of Horowitz equation
for data quality 2 ($H_a = 0.01X_a^{0.8495}$)

s.d.m. = Standard deviation of population mean
mean = Mean element concentration for all techniques reporting
Max. = Maximum element/oxide concentration reported
Min. = Minimum element/oxide concentration reported
